(54) Title: OPTICALLY PURE (-) NORCISAPRIDE FOR TREATING DIGESTIVE TRACT DISORDERS

(57) Abstract

Methods are disclosed utilizing the optically pure (-) isomer of norcisapride. This compound is a potent drug for the treatment of gastro-esophageal reflux disease, emesis, dyspepsia and other conditions while substantially reducing the concomitant liability of adverse effects associated with cisapride. The (-) isomer of norcisapride also avoids the adverse drug interactions associated with racemic cisapride and other therapeutic agents.

OPTICALLY PURE (-) NORCISAPRIDE FOR TREATING DIGESTIVE TRACT DISORDERS

1. TECHNICAL FIELD

- 5 This invention relates to novel compositions of matter containing optically pure (-) norcisapride. These compositions possess potent activity in treating gastro-esophageal reflux disease while substantially reducing adverse effects associated with the administration of racemic
- 10 cisapride including but not limited to diarrhea, abdominal cramping, cardiac depression, and elevations of blood pressure and heart rate. Additionally, these novel compositions of matter containing optically pure (-) norcisapride are useful in treating emesis and such other
- 15 conditions as may be related to the activity of (-) norcisapride as a prokinetic agent, including but not limited to dyspepsia, gastroparesis, constipation, and intestinal pseudo-obstruction, while substantially reducing adverse effects associated with the administration of racemic
- 20 cisapride. Also disclosed are methods for treating the above-described conditions in a human while substantially reducing adverse effects that are associated with cisapride, by administering the (-) isomer of norcisapride to a human in need of such treatment. Further disclosed are methods of
- 25 treating various disease states in humans by co-administering optically pure (-) norcisapride and another therapeutic agent, while unexpectedly avoiding the adverse effects associated with administering cisapride and a therapeutic agent.
- 30 The active compound of these compositions and methods is an optically pure isomer of a metabolic derivative of cisapride, which is described in Meuldermans, W. et al., *Drug Metab. Dispos.* 16(3): 410-419, 1988 and Meuldermans, W. et al., *Drug Metab. Dispos.* 16(3): 403-409, 1988.
- 35 Chemically, the active compound, of the presently disclosed compositions and methods, is the (-) isomer of the metabolic derivative of *cis*-4-amino-5-chloro-N-[1-[3-(4-

fluorophenoxy) propyl]-3-methoxy-4-piperidinyl]-2-methoxybenzamide (hereinafter referred to as "cisapride"), known as 4-amino-5-chloro-N-(3-methoxy-4-piperidinyl)-2-methoxybenzamide hereinafter referred to as "(-) 5 norcisapride." The term "(-) isomer of norcisapride" and particularly the term "(-) norcisapride" encompass optically pure and substantially optically pure (-) norcisapride. Similarly, as used herein, the terms "racemic cisapride", "racemic norcisapride" or "racemic mixture of cisapride" or 10 "racemic mixture of norcisapride" refer to the *cis* diastereomeric racemates.

Cisapride is available commercially only as the 1:1 racemic mixture of the *cis* diastereomeric racemate known as "Prepulsid™." Cisapride is available only as a mixture of 15 optical isomers, called enantiomers, *i.e.*, a mixture of *cis*(+) and *cis*(-) cisapride.

2. BACKGROUND OF THE INVENTION

2.1. Steric Relationship and Drug Action

20 Many organic compounds exist in optically active forms, *i.e.*, they have the ability to rotate the plane of plane-polarized light. In describing an optically active compound, the prefixes D and L or R and S are used to denote the absolute configuration of the molecule about its chiral center(s). The prefixes d and l or (+) and (-) are employed to designate the sign of rotation of plane-polarized light by the compound, with (-) or l meaning that the compound is levorotatory. A compound prefixed with (+) or d is dextrorotatory. For a given chemical structure, these 25 compounds, called stereoisomers, are identical except that they are mirror images of one another. A specific stereoisomer may also be referred to as an enantiomer, and a mixture of such isomers is often called an enantiomeric or racemic mixture.

30 35 Stereochemical purity is of importance in the field of pharmaceuticals, where 12 of the 20 most prescribed drugs exhibit chirality. A case in point is provided by the L-form

of the beta-adrenergic blocking agent, propranolol, which is known to be 100 times more potent than the D-enantiomer.

2.2. Pharmacologic Action

- 5 United States Patent Nos. 4,962,115, 5,057,525 and 5,137,896 (collectively "Van Daele") disclose N-(3-hydroxy-4-piperidenyl)benzamides including the *cis* and *trans* diastereomeric racemates of cisapride. Van Daele discloses that these compounds, the pharmaceutically acceptable acid 10 addition salts thereof and the stereochemically isomeric forms thereof, stimulate the motility of the gastrointestinal system. Van Daele states that the diastereomeric racemates of these compounds may be obtained separately by conventional methods and that these diastereomeric racemates may be 15 further resolved into their optical isomers. Van Daele also reports the "lowest effective concentration... whereby a significant stimulation of the acetylcholine release is noted", for *cis*(+) and *cis*(-) cisapride, to be 0.01 mg/L and 0.04 mg/L respectively, while the "lowest effective dose 20 whereby antagonistic effects of dopamine-induced gastric relaxation are observed" is reported to be 0.63 mg/L for both *cis*(+) and *cis*(-) cisapride. Therefore, Van Daele teaches that *cis*(+) and *cis*(-) cisapride have roughly identical pharmacological profiles.
- 25 Cisapride is one of a class of compounds known as benzamide derivatives, the parent compound of which is metoclopramide (See: Schapira et al., *Acta Gastroenterolog. Belg. LIII*: 446-457, 1990). As a class, these benzamide derivatives have several prominent pharmacological actions. 30 The prominent pharmacological activities of the benzamide derivatives are due to their effects on the neuronal systems which are modulated by the neurotransmitter serotonin. The role of serotonin, and thus the pharmacology of the benzamide derivatives, has been broadly implicated in a variety of 35 conditions for many years (See Phllis, J.W., "The Pharmacology of Synapses", Pergamon Press, Monograph 43, 1970; Frazer, A. et al., *Annual Rev. of Pharmacology and*

Therapeutics 30: 307-348, 1990). Thus, research has focused on locating the production and storage sites of serotonin as well as the location of serotonin receptors in the human body in order to determine the connection between these sites and 5 various disease states or conditions.

In this regard, it was discovered that a major site of production and storage of serotonin is the enterochromaffin cell of the gastrointestinal mucosa. It was also discovered that serotonin has a powerful stimulating action on 10 intestinal motility by stimulating intestinal smooth muscle, speeding intestinal transit, and decreasing absorption time, as in diarrhea. This stimulating action is also associated with nausea and vomiting.

Because of their modulation of the serotonin neuronal 15 system in the gastrointestinal tract, many of the benzamide derivatives are effective antiemetic agents and are commonly used to control vomiting during cancer chemotherapy or radiotherapy, especially when highly emetogenic compounds such as cisplatin are used (See: Costall et al., 20 *Neuropharmacology* 26: 1321-1326, 1987). This action is almost certainly the result of the ability of the compounds to block the actions of serotonin (5HT) at specific sites of action, called the 5HT₃-receptor, which was classically designated in the scientific literature as the serotonin M- 25 receptor (See: Clarke et al., *Trends in Pharmacological Sciences* 10: 385-386, 1989). Chemo- and radio-therapy may induce nausea and vomiting by the release of serotonin from damaged enterochromaffin cells in the gastrointestinal tract. Release of the neurotransmitter serotonin stimulates both 30 afferent vagal nerve fibers (thus initiating the vomiting reflex) and serotonin receptors in the chemoreceptor trigger zone of the area postrema region of the brain. The anatomical site for this action of the benzamide derivatives, and whether such action is central (CNS), peripheral, or a 35 combination thereof, remains unresolved (See: Barnes et al., *J. Pharm. Pharmacol.* 40: 586-588, 1988). Cisapride, like the other benzamide derivatives may be an effective antiemetic.

agent based on its ability to modulate the activity of serotonin at the 5HT3 receptor.

A second prominent action of the benzamide derivatives is in augmenting gastrointestinal smooth muscle activity from 5 the esophagus through the proximal small bowel, thus accelerating esophageal and small intestinal transit as well as facilitating gastric emptying and increasing lower esophageal sphincter tone (See: Decktor et al., *Eur. J. Pharmacol.* 147: 313-316, 1988). Although the benzamide 10 derivatives are not cholinergic receptor agonists per se, the aforementioned smooth muscle effects may be blocked by muscarinic receptor blocking agents such as atropine or inhibitors of neuronal transmissions such as the tetrodotoxin type which block sodium channels (See: Fernandez and 15 Massingham, *Life Sci.* 36: 1-14, 1985). Similar blocking activity has been reported for the contractile effects of serotonin in the small intestine (See: Craig and Clarke, *Brit. J. Pharmacol.* 96: 247P, 1989). It is currently believed that the primary smooth muscle effects of the 20 benzamide derivatives are the result of an agonist action upon a new class of serotonin receptors referred to as 5HT4 receptors which are located on interneurons in the myenteric plexus of the gut wall (See Clarke et al., *Trends in Pharmacological Sciences* 10: 385-386, 1989 and Dumuis et al., 25 *N. S. Arch. Pharmacol.* 340: 403-410, 1989). Activation of these receptors subsequently enhances the release of acetylcholine from parasympathetic nerve terminals located near surrounding smooth muscle fibers, and it is the combination of acetylcholine with its receptors on smooth 30 muscle membranes which is the actual trigger for muscle contraction.

Cisapride possesses similar properties to metoclopramide except that it lacks dopamine receptor blocking activity (See: Reyntjens et al., *Curr. Therap. Res.* 36: 1045-1046, 35 1984) and enhances motility in the colon as well as in the upper portions of the alimentary tract (See: Milo, *Curr. Therap. Res.* 36: 1053-1062, 1984). The colonic effects,

however, may not be completely blocked by atropine and may represent, at least in part, a direct action of the drug (See: Schuurkes et al., *J. Pharmacol Exp. Ther.* 234: 775-783, 1985). Using cultured mouse embryo coliculi neurons and 5 cAMP generation as an endpoint for designating 5HT4 activity, the EC50 concentration of racemic cisapride was 7×10^{-8} M (See: Dumuis et al., *N. S. Arch. Pharmacol.* 340: 403-410, 1989). Drugs of this class do not affect gastric acid secretion and have variable effects upon colonic motility 10 (See: Reyntjens et al., *Curr. Therap. Res.* 36: 1045-1046, 1984 and Milo, *Curr. Therap. Res.* 36: 1053-1062, 1984).

Cisapride is presently used primarily to treat gastro-esophageal reflux disease. This disease is characterized as the backward flow of the stomach contents into the esophagus. 15 One of the most important factors in the pathogenesis of gastro-esophageal reflux disease is a reduction in the pressure barrier due to the failure of the lower esophageal sphincter. Failure of the lower esophageal sphincter can arise due to a low basal pressure, sphincter relaxation, or 20 to a noncompensated increase in intragastric pressure. Other factors in the pathogenesis of the disease are delayed gastric emptying, insufficient esophageal clearing due to impaired peristalsis and the corrosive nature of the reflux material which can damage esophageal mucosa. Cisapride is 25 thought to strengthen the anti-reflux barrier and improve esophageal clearance by increasing the lower esophageal sphincter pressure and enhancing peristaltic contractions.

Because of its activity as a prokinetic agent, cisapride may also be useful to treat dyspepsia, gastroparesis, 30 constipation, postoperative ileus, and intestinal pseudo-obstruction.

Dyspepsia is a condition characterized by an impairment of the power or function of digestion that can arise as a symptom of a primary gastrointestinal dysfunction or as a 35 complication due to other disorders such as appendicitis, gallbladder disturbances, or malnutrition. Gastroparesis is a paralysis of the stomach brought about by a motor

abnormality in the stomach or as a complication of diseases such as diabetes, progressive systemic sclerosis, anorexia nervosa or myotonic dystrophy. Constipation is a condition characterized by infrequent or difficult evacuation of feces 5 resulting from conditions such as lack of intestinal muscle tone or intestinal spasticity. Post-operative ileus is an obstruction in the intestine due to a disruption in muscle tone following surgery. Intestinal pseudo-obstruction is a condition characterized by constipation, colicky pain, and 10 vomiting, but without evidence of physical obstruction.

It has been discovered that the co-administration of cisapride with another therapeutic agent causes inhibitory problems with the metabolism of cisapride by the liver. For example, ketoconazole has a pronounced effect on cisapride 15 kinetics resulting from the inhibition of the metabolic elimination of cisapride and leading to an 8-fold increase in steady-state plasma levels. (See: Lavrijsen, K., et al. "The Role of CYP3A4 in the In-vitro Metabolism of Cisapride in the Human Liver Microsomes an In-vitro and In-vivo Interactions 20 of Cisapride with Co-administered Drugs," Department of Pharmacokinetics and Drug Metabolism, Janssen Research Foundation, Beerse, Belgium). The drug-drug interaction of cisapride and another therapeutic agent can potentiate cardiovascular side effects, such as cardiotoxicity. This 25 potentiation occurs when other drugs present in the patient's system interfere with the metabolism of racemic cisapride, thereby building up racemic cisapride in the body. These drug interactions are a significant drawback to the use of racemic cisapride; in particular, because racemic cisapride 30 is often used before, during or immediately after another therapeutic agent.

In addition, the administration of cisapride to a human has been found to cause adverse effects including, tachycardia, CNS disorders, increased systolic pressure, 35 interactions with other drugs, diarrhea, abdominal cramping, and cardiac depression. Further, it has been reported that intravenous administration of racemic cisapride demonstrates

the occurrence of additional adverse (side) effects not experienced after oral administration of racemic cisapride. (See: Stacher et al. *Digestive Diseases and Sciences* 32(11):1223-1230 (1987)).

- 5 Cisapride is almost completely absorbed after oral administration to humans, but the bioavailability of the parent compound is only 40-50%, due to rapid first pass metabolism in the liver (See: Van Peer et al., in *Progress in the Treatment of Gastrointestinal Motility Disorders: The*
- 10 *Role of Cisapride.* Proceedings of a Symposium in Frankfurt. November 1986. Johnson A. G. and Lux, G. eds. *Excerpta Medica*, Amsterdam, pp. 23-29 (1988)). More than 90% of a dose of cisapride is metabolized mainly by oxidative N-dealkylation at the piperidine nitrogen or by aromatic
- 15 hydroxylation occurring on either the 4-fluorophenoxy or benzamide rings. It is the piperidinylbenzamid moiety of the metabolized cisapride which is identified as norcisapride. (See: Meuldermans, W. et al., *Drug Metab. Dispos.* 16(3): 410-419, 1988 and Meuldermans, W. et al., *Drug Metab. Dispos.* 20 16(3): 403-409, 1988). The metabolism of cisapride to norcisapride is believed to occur as follows:

25

30

35

Norcisapride is the main urinary metabolite comprising 50-80% of the drug found in the urine of humans 72 hours after dosing. (See: Meuldermans, W. et al., *Drug Metab. Dispos.* 16(3): 410-419, 1988). Short duration of action, as seen with cisapride, can often be associated with erratic pharmacological effects following oral administration of compounds.

There has been an effort to develop a compound having the benefits of racemic cisapride without having the disadvantages of racemic cisapride which are known to those skilled in the art, such as those mentioned above. For example, PCT Application WO94-01112, published on January 20, 1994 discloses the use of the optically pure (-) isomer of cisapride to treat gastro-esophageal reflux disease, nausea or vomiting, gastrointestinal motility dysfunction or disorders of the central nervous system while avoiding the adverse effects associated with racemic cisapride.

Thus, it would be particularly desirable to find a compound with the advantages of cisapride which would not have the aforementioned disadvantages.

3. SUMMARY OF THE INVENTION

It has now been discovered that novel compositions of matter containing the optically pure (-) isomer of norcisapride are useful in treating gastro-esophageal reflux disease while substantially reducing adverse effects associated with the administration of racemic cisapride, including but not limited to diarrhea, abdominal cramping, cardiac depression and elevations of blood pressure and heart rate. It has also been discovered that optically pure (-) norcisapride is an effective antiemetic agent, useful as an adjunctive therapy in cancer treatment to alleviate nausea and vomiting induced by chemo- or radio-therapeutics, while substantially reducing the above-described adverse effects associated with the administration of racemic cisapride. It has also been discovered that these novel compositions of matter containing optically pure (-) norcisapride are useful

in treating dyspepsia and such other conditions as may be related to the activity of (-) norcisisapride as a prokinetic agent, e.g., gastroparesis, constipation, post-operative ileus, and intestinal pseudo-obstruction, while substantially reducing the above-described adverse effects associated with the administration of racemic cisapride.

The present invention also includes methods for treating the above-described conditions in a human while substantially reducing adverse effects that are associated with racemic cisapride, by administering the optically pure (-) isomer of norcisisapride to said human. The present invention also includes methods and compositions which demonstrate an improved bioavailability over racemic cisapride irrespective of the mode of administration. Furthermore, the present invention also included methods and compositions for treating human disease states by having the unexpected benefit of being able to administer both optically pure (-) norcisisapride and another therapeutic agent without the inhibitory effects commonly associated with the co-administration of cisapride and another therapeutic agent e.g., adverse drug interaction.

The use of optically pure (-) norcisisapride has been found to be superior to racemic cisapride, racemic norcisisapride or optically pure (-) cisapride in treating the above-mentioned disease states.

25

4. DETAILED DESCRIPTION OF THE INVENTION

The present invention encompasses a method of treating gastro-esophageal reflux disease in a human, while substantially reducing the concomitant liability of adverse effects associated with the administration of racemic cisapride, which comprises administering to a human in need of such treatment, an effective amount of (-) norcisisapride, or a pharmaceutically acceptable salt thereof, substantially free of its (+) stereoisomer, said amount being sufficient to alleviate said reflux disease, but insufficient to cause said adverse effects associated with cisapride.

The present invention also encompasses a composition for the treatment of a human suffering from gastro-esophageal reflux disease, which comprises an effective amount of (-) norcisapride, or a pharmaceutically acceptable salt thereof, substantially free of its (+) stereoisomer, said amount being sufficient to alleviate said reflux disease, but insufficient to cause adverse effects associated with racemic cisapride.

The present invention further encompasses a method of eliciting an antiemetic effect in a human, while substantially reducing the concomitant liability of adverse effects associated with the administration of racemic norcisapride, which comprises administering to a human in need of such antiemetic therapy, an effective amount of (-) norcisapride, or a pharmaceutically acceptable salt thereof, substantially free of its (+) stereoisomer, said amount being sufficient to alleviate nausea and vomiting but insufficient to cause adverse effects associated with the administration of racemic cisapride.

In addition, the present invention encompasses an antiemetic composition for the treatment of a human in need of antiemetic therapy, which comprises an effective amount of (-) norcisapride, or a pharmaceutically acceptable salt thereof, substantially free of its (+) stereoisomer, said amount being sufficient to alleviate nausea and vomiting but insufficient to cause adverse effects associated with the administration of racemic cisapride.

A further aspect of the present invention includes a method of treating a condition caused by gastrointestinal motility dysfunction in a human, while substantially reducing the concomitant liability of adverse effects associated with the administration of cisapride, which comprises administering to a human in need of treatment for gastrointestinal motility dysfunction, an effective amount of (-) norcisapride, or a pharmaceutically acceptable salt thereof, substantially free of its (+) stereoisomer, said amount being sufficient to alleviate said condition but insufficient to cause adverse effects associated with the

administration of racemic cisapride. Conditions caused by gastrointestinal motility dysfunction in a human include, but are not limited to, dyspepsia, gastroparesis, constipation, postoperative ileus, and intestinal pseudo-obstruction.

5 Furthermore, the present invention includes a composition for treating a condition caused by gastrointestinal motility dysfunction in a human, which comprises an effective amount of (-) norcisapride, or a pharmaceutically acceptable salt thereof, substantially free 10 of its (+) stereoisomer, said amount being sufficient to alleviate said condition caused by gastrointestinal motility dysfunction, but insufficient to cause adverse effects associated with the administration of racemic cisapride.

The present invention encompasses a novel composition of 15 matter comprising (-) norcisapride or a pharmaceutically acceptable salt thereof, substantially free of its (+) stereoisomer, wherein said composition provides a higher bioavailability of the active compound than does the racemic mixture of cisapride, the isomers of cisapride, or the 20 racemic mixture of norcisapride. The bioavailability of (-) norcisapride is found to be higher than that of racemic cisapride, its isomers or racemic norcisapride irrespective of the mode of administration. Further, these novel compositions are used to treat a variety of disorders, as 25 described above, while substantially reducing adverse effects which are caused by the administration of racemic cisapride. These novel compositions may optionally contain a pharmaceutically acceptable carrier or combinations thereof as described below.

30 The increased bioavailability of (-) norcisapride allows for a more effective pharmacodynamic profile than racemic cisapride or racemic norcisapride and a more effective management of the disease being treated. For example, a more effective management of disorders is achieved with the 35 administration of (-) norcisapride, since dosing frequency can be reduced. This would facilitate, e.g., overnight treatment while the patient is asleep. Similarly, a lower

dose frequency is beneficial when (-) norcisisapride is used prophylactically or as a treatment for emesis in cancer patients.

- Therefore, the present invention further encompasses a 5 method for treating gastro-esophageal reflux disease in a human while achieving higher bioavailability than racemic cisapride, (-) cisapride or racemic norcisisapride which comprises administering to a human in need of treatment from such a disorder, an effective amount of (-) norcisisapride, or 10 a pharmaceutically acceptable salt thereof, substantially free of its (+) stereoisomer, said amount being sufficient to alleviate said reflux disease and said amount having increased bioavailability than racemic cisapride, racemic norcisisapride or (-) cisapride.
- 15 The present invention also encompasses a method of eliciting an antiemetic effect in a human while achieving a higher bioavailability than racemic cisapride, (-) cisapride or racemic norcisisapride which comprises administering to a human in need of antiemetic therapy, an effective amount of 20 (-) norcisisapride, or a pharmaceutically acceptable salt thereof, substantially free of its (+) stereoisomer, said amount being sufficient to alleviate nausea and vomiting and said amount having higher bioavailability than racemic cisapride, racemic norcisisapride or (-) cisapride.
- 25 The present invention further encompasses a method of treating a condition caused by gastrointestinal motility dysfunction in a human, while achieving higher bioavailability than racemic cisapride, (-) cisapride or norcisisapride, which comprises administering to a human in 30 need of treatment for gastrointestinal motility dysfunction, an effective amount of (-) norcisisapride, or a pharmaceutically acceptable salt thereof, substantially free of its (+) stereoisomer, said amount being sufficient to alleviate said condition and said amount having a higher 35 bioavailability than racemic cisapride, racemic norcisisapride or (-) cisapride.

In addition, the present invention encompasses methods for treating the above-described conditions, comprising administering to a human in need of treatment for such a condition, an effective amount of (-) norcisapride, or a 5 pharmaceutically acceptable salt thereof, substantially free of its (+) stereoisomer, said amount having increased bioavailability over the racemic cisapride, (-) cisapride, or racemic norcisapride mixture and being sufficient to alleviate said condition but being insufficient to cause 10 adverse effects associated with racemic norcisapride.

The invention also encompasses the reduction of the cardiovascular side effects which is potentiated by the co-administration of cisapride with another therapeutic agent. There can be a drug-drug interaction between racemic 15 cisapride and other therapeutic agents. For example, therapeutics which interfere with the metabolism of racemic cisapride, cause cisapride to build up in the body. This build up can cause or enhance the adverse cardiovascular effects known to be associated with racemic cisapride such as 20 cardiotoxicity. Thus, the presence of such therapeutics either from co-administration or sequential administration before or after racemic cisapride can cause or enhance the adverse effects of racemic cisapride. The use of (-) norcisapride has unexpectedly been found to reduce these 25 adverse side effects. It is believed that (-) norcisapride both reduces the adverse drug interactions which occur with racemic norcisapride thereby indirectly reducing adverse effects as well as reducing the adverse effects of racemic cisapride itself. Thus, (-) norcisapride can be co- 30 administered with drugs such as ketoconazole an agent known to inhibit the cytochrome P450 system, which is responsible for the metabolism of cisapride, without causing or increasing the adverse cardiovascular side effects of racemic cisapride.

35 Thus, the present invention encompasses methods for treating the above described disorders in a human, which comprises administering to a human (a) an effective amount of

(-) norcisapride or a pharmaceutically acceptable salt thereof, substantially free of its (+) stereoisomer; and (b) another therapeutic agent. The inhibitory co-administration problems associated with the administration of cisapride and 5 another therapeutic agent can be overcome by administering optically pure (-) norcisapride in conjunction with the therapeutic agent. Therefore, a physician does not have to be concerned with the cardiotoxic side effects when administering norcisapride with another drug. These 10 disorders include, but are not limited to gastro-esophageal reflux, nausea or vomiting, gastrointestinal motility dysfunctions or a disorders of the central nervous system. Other therapeutic agents to be used in conjunction with or which may be administered during treatment with (-) 15 norcisapride include, but are not limited to antifungal, antiviral, antibacterial, antitumor or antihistamine agents or selective serotonin uptake inhibitors. Examples of an antifungal agents include, but are not limited to ketoconazole, itraconazole and amphotericin B. Examples of 20 an antibacterial agents include, but are not limited to temafloxacin, lomefloxacin, cefadroxil and erythromycin. Examples of an antiviral agents include, but are not limited to ribavirin, rifampicin, AZT, DDI, acyclovir and ganciclovir. Examples of an antitumor agents include, but 25 are not limited to doxorubicin and cisplatin. Among other agents which may be co-administered with (-) norcisapride include, but are not limited to digoxin, diazepam, ethanol, acenocoumarol, fluoxetine, ranitidine, paracetamol, terfenadine, astemizole, propranolol and other agents known 30 to inhibit the cytochrome P450 system.

The observation that cisapride enters the central nervous system and binds to 5HT4 receptors indicates that cisapride may have centrally-mediated effects. As was shown by Dumuis et al., N.S. Arch. Pharmacol. 340: 403-410, 1989, 35 cisapride is a potent ligand at 5HT4 receptors, and these receptors are located in several areas of the central nervous system. Modulation of serotonergic systems has a variety of

behavioral effects. Norcisapride, the metabolic derivative of cisapride, therefore, could be therapeutically useful in the treatment of: 1) cognitive disorders, including but not limited to Alzheimer's disease; 2) behavioral disorders, 5 including but not limited to schizophrenia, mania, obsessive-compulsive disorder, and psychoactive substance use disorders; 3) mood disorders, including but not limited to depression and anxiety; and 4) disorders of control of autonomic function, including but not limited to essential 10 hypertension and sleep disorders.

The available racemic mixture of cisapride (*i.e.*, a 1:1 racemic mixture of the two *cis* enantiomers) possesses prokinetic and antiemetic activity, and provides therapy and a reduction of symptoms in a variety of conditions and 15 disorders related to gastrointestinal motility dysfunction; however, this racemic mixture, while offering the expectation of efficacy, causes adverse effects and has a relatively short duration of action. In addition, there are adverse cardiovascular effects known to be associated with the 20 administration of cisapride in the presence of another therapeutic agent. A drug-drug interaction can occur which prevents the metabolism of cisapride causing it to accumulate in the body; this accumulation can result in cardiotoxicity. Specifically, racemic cisapride has a potential for adverse 25 drug interactions with drugs that inhibit the metabolism of cisapride by the cytochrome P450 system, *e.g.* ketoconazole. Utilizing the substantially optically pure or optically 30 pure isomer of (-) norcisapride results in clearer dose related definitions of efficacy, diminished adverse effects, and accordingly, an improved therapeutic index as well as a higher bioavailability than racemic cisapride, racemic norcisapride or (-) *cis* cisapride. Such utilization also allows the treatment of various human disease states with both optically pure (-) norcisapride and another therapeutic 35 agent. It is therefore more desirable to use the (-) isomer of norcisapride than to administer racemic cisapride, racemic norcisapride or (-) *cis* cisapride.

The term "bioavailability" refers to the rate, extent, and duration with which an active drug or metabolite enters and remains in the general circulation, thereby permitting access to the site of action. Higher bioavailability may be achieved by, e.g., increasing the drug's duration of action.

The term "adverse effects" includes, but is not limited to, gastrointestinal disorders such as diarrhea, abdominal cramping, and abdominal grumbling; tiredness; headache; cardiac depression; increased systolic pressure; increased heart rate; neurological and CNS disorders; and adverse effects that result from the interaction of cisapride with other drugs that inhibit the metabolism of cisapride by the cytochrome P450 system including but not limited to ketoconazole, digoxin, diazepam, ethanol, acenocoumarol, cimetidine, ranitidine, paracetamol, fluoxetine, terfenadine, astemizole and propranolol.

The term "substantially free of its stereoisomer" as used herein means that the compositions contain at least 90% by weight of (-) norcisapride and 10% by weight or less of (+) norcisapride. In a more preferred embodiment the term "substantially free of the (+) stereoisomer" means that the composition contains at least 99% by weight of (-) norcisapride, and 1% or less of (+) norcisapride. In a most preferred embodiment, the term "substantially free of its (+) stereoisomer" as used herein means that the composition contains greater than 99% by weight of (-) norcisapride. These percentages are based upon the total amount of norcisapride in the composition. The terms "substantially optically pure (-) isomer of norcisapride" or "substantially optically pure norcisapride" and "optically pure isomer of norcisapride" and "optically pure norcisapride" are encompassed by the above-described amounts.

The term "gastro-esophageal reflux disease as used herein means the incidence of, and the symptoms of, those conditions causing the backward flow of the stomach contents into the esophagus.

The terms "eliciting an antiemetic effect" and "antiemetic therapy" as used herein mean providing relief from or preventing the symptoms of nausea and vomiting induced spontaneously or associated with emetogenic cancer 5 chemotherapy or irradiation therapy.

The term "treating a condition caused by gastrointestinal motility dysfunction" as used herein means treating the symptoms and conditions associated with this disorder which include, but are not limited to, dyspepsia, 10 gastroparesis, constipation, postoperative ileus, and intestinal pseudo-obstruction.

The term "prokinetic" as used herein means the enhancement of peristalsis in, and thus the movement through the gastrointestinal tract.

15 The term "dyspepsia" as used herein means a condition characterized by an impairment of the power or function of digestion that can arise as a symptom of a primary gastrointestinal dysfunction or as a complication due to other disorders such as appendicitis, gallbladder 20 disturbances, or malnutrition.

The term "gastroparesis" as used herein means a paralysis of the stomach brought about by a motor abnormality in the stomach or as a complication of diseases such as diabetes, progressive systemic sclerosis, anorexia nervosa, 25 or myotonic dystrophy.

The term "constipation" as used herein means a condition characterized by infrequent or difficult evacuation of feces resulting from conditions such as lack of intestinal muscle tone or intestinal spasticity.

30 The term "post-operative ileus" as used herein means an obstruction in the intestine due to a disruption in muscle tone following surgery.

The term "intestinal pseudo-obstruction" as used herein means a condition characterized by constipation, colicky 35 pain, and vomiting, but without evidence of physical obstruction.

The term "co-administration" as used herein means the administration of two therapeutic agents either simultaneously, concurrently or sequentially with no specific time limits.

- 5 The chemical synthesis of the racemic mixture of cisapride can be performed by the method described in European Patent Application No. 0,076,530 A2 published April 13, 1983, U.S. Patent Nos. 4,962,115, 5,057,525 and 5,137,896 and in Van Daele et al., *Drug Development Res.* 8: 225-232
- 10 (1986), the disclosures of which are incorporated herein by reference. The metabolism of cisapride to norcisapride is described in Meuldermans, W. et al., *Drug Metab. Dispos.* 16(3): 410-419, 1988 and Meuldermans, W. et al., *Drug Metab. Dispos.* 16(3): 403-409, 1988, the disclosures of which are
- 15 incorporated herein by reference. Norcisapride can be synthesized in accordance with standard organic chemistry techniques. One skilled in the art can synthesize cisapride or norcisapride by the teachings of EP 0,076,530 A2 and U.S. Patent No. 5,137,896 to Van Daele.
- 20 The (-) isomer of norcisapride may be obtained from its racemic mixture by resolution of the enantiomers using conventional means such as from an optically active resolving acid. See, for example, "Enantiomers, Racemates and Resolutions," by J. Jacques, A. Collet, and S.H. Wilen,
- 25 (Wiley-Interscience, New York, 1981); S.H. Wilen, A. Collet, and J. Jacques, *Tetrahedron*, 33, 2725 (1977); and "Stereochemistry of Carbon Compounds, by E.L. Eliel (McGraw-Hill, NY, 1962) and S.H. Wilen, page 268, in "Tables of Resolving Agents and Optical Resolutions" (E.L. Eliel, Ed.
- 30 Univ. of Notre Dame Press, Notre Dame, IN, 1972). Furthermore, the optically pure isomer of norcisapride can be prepared from the racemic mixture by enzymatic biocatalytic resolution. See, for example, United States Patent Nos. 5,057,427 and 5,077,217, the disclosures of which are
- 35 incorporated by reference.

The magnitude of a prophylactic or therapeutic dose of (-) norcisapride in the acute or chronic management of

diseases and/or disorders described herein will vary with the severity of the condition to be treated, and the route of administration. The dose, and perhaps the dose frequency, will also vary according to the age, body weight, and response of the individual patient. In general, the total daily dose range for (-) norcisapride, for the conditions described herein, is from about 1 mg to about 200 mg, in single or divided doses. Preferably, a daily dose range should be between about 5 mg to about 100 mg, in single or 5 divided doses, while most preferably, a daily dose range should be between about 5 mg to about 75 mg, in single or divided doses. It is preferred that the doses are administered from 1 to 4 times a day. In managing the patient, the therapy should be initiated at a lower dose, 10 perhaps about 5 mg to about 10 mg, and increased up to about 50 mg or higher depending on the patient's global response. It is further recommended that children, and patients over 65 years, and those with impaired renal or hepatic function, initially receive low doses, and that they be titrated based 15 on individual response(s) and blood level(s). It may be necessary to use dosages outside these ranges in some cases as will be apparent to those skilled in the art. Further, it is noted that the clinician or treating physician will know how and when to interrupt, adjust, or terminate therapy in 20 conjunction with individual patient response. The terms "an amount sufficient to alleviate said reflux disease, but insufficient to cause adverse effects", "an amount sufficient to alleviate nausea and vomiting but insufficient to cause adverse effects", and "an amount sufficient to alleviate said 25 condition caused by gastrointestinal motility dysfunction, but insufficient to cause adverse effects" are encompassed by the above-described dosage amounts and dose frequency schedule.

Any suitable route of administration may be employed for 30 providing the patient with an effective dosage of norcisapride. For example, oral, rectal, parenteral (subcutaneous, intramuscular, intravenous), transdermal, and

like forms of administration may be employed. Dosage forms include tablets, troches, dispersions, suspensions, solutions, capsules, patches, and the like.

The pharmaceutical compositions of the present invention 5 comprise (-) norcisapride as the active ingredient, or a pharmaceutically acceptable salt thereof, and may also contain a pharmaceutically acceptable carrier, and optionally, other therapeutic ingredients

The term "pharmaceutically acceptable salts" or "a 10 pharmaceutically acceptable salt thereof" refer to salts prepared from pharmaceutically acceptable nontoxic acids or bases including inorganic acids and bases and organic acids and bases. Since the compound of the present invention is basic, salts may be prepared from pharmaceutically acceptable 15 non-toxic acids. Suitable pharmaceutically acceptable acid addition salts for the compound of the present invention include acetic, benzenesulfonic (besylate), benzoic, camphorsulfonic, citric, ethenesulfonic, fumaric, gluconic, glutamic, hydrobromic, hydrochloric, isethionic, lactic, 20 maleic, malic, mandelic, methanesulfonic, mucic, nitric, pamoic, pantothenic, phosphoric, succinic, sulfuric, tartaric acid, p-toluenesulfonic, and the like. Preferred acid addition salts are the chloride and sulfate salts. In the most preferred embodiment, (-) norcisapride is administered 25 as the free base.

The compositions of the present invention include compositions such as suspensions, solutions and elixirs; aerosols; or carriers such as starches, sugars, microcrystalline cellulose, diluents, granulating agents, 30 lubricants, binders, disintegrating agents, and the like, in the case of oral solid preparations (such as powders, capsules, and tablets) with the oral solid preparations being preferred over the oral liquid preparations. A preferred oral solid preparation is capsules. The most preferred oral 35 solid preparation is tablets.

Because of their ease of administration, tablets and capsules represent the most advantageous oral dosage unit

form, in which case solid pharmaceutical carriers are employed. If desired, tablets may be coated by standard aqueous or nonaqueous techniques.

In addition to the common dosage forms set out above, 5 the compounds of the present invention may also be administered by controlled release means and/or delivery devices such as those described in U.S. Patent Nos.: 3,845,770; 3,916,899; 3,536,809; 3,598,123; and 4,008,719, the disclosures of which are hereby incorporated by 10 reference.

Pharmaceutical compositions of the present invention suitable for oral administration may be presented as discrete units such as capsules, cachets, or tablets, or aerosols sprays, each containing a predetermined amount of the active 15 ingredient, as a powder or granules, or as a solution or a suspension in an aqueous liquid, a non-aqueous liquid, an oil-in-water emulsion, or a water-in-oil liquid emulsion. Such compositions may be prepared by any of the methods of pharmacy, but all methods include the step of bringing into 20 association the active ingredient with the carrier which constitutes one or more necessary ingredients. In general, the compositions are prepared by uniformly and intimately admixing the active ingredient with liquid carriers or finely divided solid carriers or both, and then, if necessary, 25 shaping the product into the desired presentation.

For example, a tablet may be prepared by compression or molding, optionally, with one or more accessory ingredients. Compressed tablets may be prepared by compressing in a suitable machine the active ingredient in a free-flowing form 30 such as powder or granules, optionally mixed with a binder, lubricant, inert diluent, surface active or dispersing agent. Molded tablets may be made by molding, in a suitable machine, a mixture of the powdered compound moistened with an inert liquid diluent. Desirably, each tablet contains from about 1 35 mg to about 100 mg of the active ingredient, and each cachet or capsule contains from about 1 mg to about 50 mg of the active ingredient. Most preferably, the tablet, cachet or

capsule contains either one of three dosages, i.e., about 5 mg, about 10 mg or about 25 mg of the active ingredient.

The invention is further defined by reference to the following examples, describing in detail the preparation of 5 the compound and the compositions of the present invention, as well as their utility. It will be apparent to those skilled in the art that many modifications, both to materials and methods, may be practiced without departing from the purpose and interest of this invention.

10

5. EXAMPLES

5.1. EXAMPLE 1

Determination of Efficacy

The relative activities of optically pure and racemic 15 cisapride and norcisapride are determined by a pharmacological study in dogs. Evaluation of these compounds is based on their relative potencies in a test to measure gastric emptying as an index of prokinetic activity in the stomach. The compounds are dissolved or suspended in 0.5% 20 methylcellulose and administered at varying doses via an indwelling gastric fistula to adult beagle dogs. The compounds are given 60 minutes prior to the administration via fistula of a liquid test meal containing the dye phenol red. The gastric contents are collected 5 minutes later via 25 gravity drainage through the fistula. Gastric emptying during this period may be calculated according to the formula of Debas (See: Fitzpatrick et al., J. Pharmacol. Exp. Ther. 254: 450-455, 1990) which takes into account both the volume of meal collected and the concentration of the dye. The 30 relative potencies of the optical isomer of cisapride and norcisapride as well as racemic cisapride and norcisapride are assessed via standard parallel line assays.

35

5.2. EXAMPLE 2

Bioavailability

A single dose of test substance or vehicle is administered to male beagle dogs either intravenously as a

bolus over one minute using a 23 ga butterfly needle into the saphenous vein, or as a single dose via oral gavage. 2.0 ml of whole blood is collected from each dog prior to and at intervals of 0.083, 0.25, 0.5, 1, 2, 3, 4, 6, 9, 12, and 24 hours following the intravenous or oral administration of the optical isomers or racemic mixture of cisapride or of norcisapride. The dogs are placed in sling-restraint prior to administration of test substance and are transferred to metabolic cages following collection of the 0.083 hour blood sample. All blood samples are collected from an angiocatheter placed in a cephalic vein on the morning of the experiment.

The blood is drawn into a 3 cc syringe. The first 1.0-2.0 ml of blood is discarded. The next 2.0 ml of whole blood is quickly transferred to a heparinized tube. The heparinized tubes are kept on ice until the blood is added. After adding the blood to the tube, the contents of the tube are mixed and centrifuged to obtain plasma. The plasma is carefully decanted and transferred to a test tube labelled with: the animal number, the dose of test substance administered, the route of administration, the date of administration, and the time of blood collection. The tubes are stored at -20° C until analysis.

Analysis of the concentration of the optical isomers or racemates of norcisapride in each plasma sample is determined using high performance liquid chromatography. For each test substance the plasma concentration vs. sample time is plotted for both routes of administration. The oral bioavailability of each test substance is determined by comparing the C_{max} and AUC for the oral route of administration versus those for the i.v. route. The $t_{1/2}$ for each test substance by both routes is calculated as an indicator of duration of action.

35

5.3. EXAMPLE 3

5HT3 Receptor Binding

The affinity of compounds for the 5HT3 receptor is assessed via a radioligand binding assay using animal

membranes that are rich in such receptors, e.g., those derived from the cerebral cortex of rat brains (See: Fitzpatrick et al., *J. Pharmacol. Exp. Ther.* 254: 450-455, 1990). Plasma membranes from the animal source are 5 equilibrated in test tubes with solutions containing a radioactive 5HT3 receptor ligand and various concentrations of (-) cisapride, (+) cisapride, racemic cisapride, (-) norcisapride, (+) norcisapride or racemic norcisapride. After incubation for 30 minutes, the membranes are isolated 10 on a filter and the degree of inhibition of radioactive ligand binding is determined. Based on the results obtained, the concentration of each compound which inhibits ligand binding by 50% (the IC50) is calculated.

15

5.4. EXAMPLE 4

5HT4 Receptor Agonist A

Agonist activity at 5HT4 receptor sites is assessed using an assay based on the ability of active compounds to increase cyclic AMP production in mouse embryo colloculi 20 neurones grown in tissue culture (See: Dumuis et al., *N. S. Arch. Pharmacol.* 340: 403-410, 1989). (-) cisapride, (+) cisapride, racemic cisapride, (-) norcisapride, (+) norcisapride and racemic norcisapride, at varying concentrations, are incubated with these cells for 10 minutes 25 in the presence of the cAMP precursor substance, ATP. At the end of this period, the degree of formation of cAMP is assessed. The concentration of agonist compound required to increase the formation of cAMP by 50% of the maximal possible (the EC50) is then calculated.

30

5.5. EXAMPLE 5

Determination of Cardiovascular Effects

Unanesthetized normotensive or spontaneously hypertensive rats (SHR) are used. Blood pressure is recorded 35 indirectly in a temperature-controlled environment before, and 1, 2, and 4 hours after, the test substance is

administered by an appropriate route. The test substances are racemic, (-) and (+) cisapride and racemic, (-) and (+) norcisapride. Changes in systolic blood pressure by more than 10% (>10) at any two of the aforementioned three consecutive time points is considered significant.

Tachycardia is also studied. In the same normotensive or spontaneously hypertensive rats, heart rate is recorded by a cardiograph immediately after the blood pressure recordings. An increase in heart rate greater than 20 percent (>20) from pretreatment control readings is considered significant.

Similar studies can be performed using guinea pigs or piglets.

5.6. EXAMPLE 6

Colonic Propulsive Motility

The purpose of this study is to demonstrate and characterize the pharmacological effects of experimental compounds on colonic propulsive motility in the mouse. The test is based on the reflex expulsion of a glass bead from the distal colon, which is indicative of drug effects on the reflex arc. This test is useful in evaluating whether diarrhea is a side effect, and may provide evidence of compounds lacking this effect.

Female albino Swiss CD-1 mice, 18-24 grams, are obtained. They are housed in groups of 5-10 in plastic cages maintained in a climate-controlled room with water and food available *ad libitum*. Mice are fasted for one hour prior to oral administration of test compounds. Mice are administered drug (calculated as base weight) or vehicle by the appropriate route. Control animals receive a similar quantity of the appropriate vehicle.

The experimental compound is administered orally at the appropriate dose(s) and followed 30 minutes later by the insertion of a single 3 mm glass bead 2 cm into the distal colon of each mouse. Mice are marked for identification and placed in large glass beakers for observation. The time required for expulsion of the bead is noted for each mouse with a cut-off period of 30 minutes. Mice not expelling the

- bead by that time are sacrificed in a carbon dioxide chamber and necropsied to confirm the presence of the bead within the lumen of the colon. Mice for which bead localization within the lumen could not be confirmed (perforation) are not included in the results. Mice receiving vehicle usually expel the bead in a range of 4-6 minutes. Experimental compounds are: racemic cisapride, (+) cisapride, (-) cisapride, racemic norcisapride, (+) norcisapride and (-) norcisapride.
- Data are analyzed for difference from vehicle control using two-way analysis of variance and Fisher's least significant difference comparison (LSD) test. ED₅₀s (the dose causing a 50% reduction of time for expulsion) for compounds having significant activity are calculated using regression analysis.

5.7. EXAMPLE 7

Gastric Emptying

Gastric emptying is evaluated by determining the emptying of 1 mm polystyrene beads from the stomach of fasted rats. Evaluation of gastric emptying in the rat is an important pharmacological parameter. Drug induced inhibition of gastric emptying in the rat is often a characteristic of compounds producing emesis or other gastrointestinal symptoms in other species. Drugs speeding gastric emptying can be useful therapeutically for a number of gastrointestinal dysfunctions. This test is sensitive to the inhibition of gastric emptying produced by anticholinergics and some centrally acting compounds, and to the prokinetic activity of compounds such as metoclopramide, domperidone and cisapride.

Male or female Sprague-Dawley rats, 80-150 grams, are obtained and quarantined for 7 days. They are housed individually with water available ad libitum. Food is withheld 24 hours prior to the study. Rats are administered drug (calculated as base weight) by the appropriate route.

Rats are administered (+), (-), or racemic cisapride, or (+), (-), or racemic norcisapride by the appropriate route.

30 or 60 minutes later, ten 1 mm polystyrene pellets are administered by gavage. For tests evaluating inhibition of gastric emptying, rats are sacrificed 3 hours after pellet administration. To test for potential augmentation of 5 emptying, rats are sacrificed 30 minutes after pellet administration. Rats are sacrificed in a carbon dioxide chamber, and the stomachs are removed. The number of the pellets remaining in the stomach are counted. In control studies, 90% of pellets are still in the stomach after 30 10 minutes, and fewer than 10% of pellets are in the stomach after 3 hours.

Data are analyzed for difference from vehicle control using two-way analysis of variance and Fisher's least significant difference comparison (LSD) test. ED₅₀s (the dose 15 causing a 50% prolongation of time for expulsion) for compounds having significant activity are calculated using regression analysis.

20

5.8. EXAMPLE 8

Central Nervous System Effects

The effects of racemic and optically pure enantiomers of norcisapride and cisapride on memory can be tested using the method described by Forster et al., *Drug Development Research*, 11:97-106 (1987). In this technique, pharmacologic 25 effects of drugs on memory in mice are tested using a "discriminated escape" paradigm. Groups of mice are designated for vehicle and drug treatment, and each mouse is trained to enter the correct goal arm of a T-maze to escape an 0.8 mA foot shock delivered through the floor of the 30 apparatus. The mice are dosed with vehicle or test compound during the training period.

The mice are initially given a preference trial in which entry to either goal arm will result in termination of foot shock, but they are trained to escape the shock via the arm 35 opposite their preference in all subsequent trials. Mice are trained ("minimal training") until a learning criterion of two consecutive correct choices is met.

One week after training, all mice are tested for retention of the discrimination. The measure of retention is the percentage of correct choice trials, i.e., those in which the mouse enters the arm of the maze in which he does not receive a foot shock. Retention of discrimination is compared for the groups of mice that have been dosed, respectively, with (-) cisapride, (+) cisapride, racemic cisapride, (-) norcisapride, (+) norcisapride, racemic norcisapride, and vehicle.

Effects of racemic and optically pure enantiomers of cisapride or norcisapride on sleep can be tested using electroencephalographic analysis. Groups of rats or dogs are prepared for electroencephalographic recordings by implanting cranial electrodes under general anesthesia, and then connecting these electrodes to an electroencephalic recording device after the effects of the anesthesia have worn off. These recordings are made continuously, and are used to classify the sleep state of the animal. Sleep states are classified as either "awake," "slow-wave sleep," or "REM sleep." The percentage of each of the sleep states following administration of placebo, cisapride isomers or racemate, or norcisapride isomers or racemate is compared to evaluate the sleep-regulating effect of the tested drug.

Blockade of the conditioned avoidance response (CAR) can be used to demonstrate the ability of racemic and optically pure cisapride or norcisapride to treat the symptoms of schizophrenia. This testing procedure employs rats that are trained to avoid a foot shock by pressing a lever at the start of a test period. The start of the test period is signaled by a non-noxious stimulus (light or buzzer). Animals that are fully trained in this procedure will avoid the foot shock more than 90% of the time. Compounds that are effective antipsychotics will block this conditioned avoidance response. Thus, (+), (-), and racemic cisapride and norcisapride are tested by administering fixed doses of test and reference compounds to trained rats and then determining their relative effects on conditioned avoidance.

Racemic and optically pure cisapride and norcisapride are tested for antidepressant activity using the mouse tail suspension test (Steru et al., *Psychopharmacology* 85:367-370, 1985). A fixed dose of (+), or (-) racemic cisapride or (+), 5 (-) or racemic norcisapride or a reference drug is administered to a mouse, and the mouse is suspended about 15 cm above the table from a hook that is taped to the tail. The animal's movements are recorded on a polygraph. Mice typically struggle for a few minutes, and then bouts of 10 movement are interspersed with periods of immobility ("behavioral despair"). A decrease in the total duration of immobility during a standard test session signifies potential antidepressant activity of the test compound.

Racemic and optically pure cisapride and norcisapride 15 are tested for effects on psychoactive substance use disorders by administering test or reference compound to laboratory animals, e.g., rats, that are trained to press a lever in anticipation of receiving one of a variety of psychoactive substances ("drug self-administration").

20 Separate animals that have been trained to self-administer cocaine, alcohol, and morphine are employed in this study. Fixed ratios and progressive ratios are used in setting the amount of lever pressing that is required for the animal to receive the substance. (+), (-), and racemic cisapride or 25 norcisapride are administered at fixed doses before the standard self-administration session. A decrease in the number of self-administrations or a reduction in the lever press/reward ratio indicates that the test compound has utility in treating psychoactive substance use disorders.

30

5.9. EXAMPLE 9
Oral Formulation

Tablets

	Formula	Quantity per Tablet in mg.		
		A	B	C
5	Active Ingredient (-) norcisapride	5.0	10.0	25.0
10	Lactose BP	62.0	57.0	42.0
10	Starch BP	20.0	20.0	20.0
10	Microcrystalline Cellulose	10.0	10.0	10.0
15	Hydrogenated Vegetable Oil	1.5	1.5	1.5
15	Polyvinylpyrrolidinone	1.5	1.5	1.5
15	Compression Weight	100.0	100.0	100.0

The active ingredient, (-) norcisapride, is sieved through a suitable sieve and blended with the lactose until a uniform blend is formed. Suitable volumes of water are added and the powders are granulated. After drying, the granules are then screened and blended with the remaining excipients. The resulting granules are then compressed into tablets of desired shape. Tablets of other strengths may be prepared by altering the ratio of active ingredient to the excipient(s) or the compression weight.

It may be apparent to those skilled in the art that modifications and variations of the present invention are possible in light of the above disclosure. It is understood that such modifications are within the spirit and scope of the invention, which is limited and defined only by the appended claims.

What is claimed is:

1. A pharmaceutical composition for the treatment of a disease state in a human which comprises an effective amount of (-) norcisapride or a pharmaceutically acceptable salt thereof, substantially free of its (+) stereoisomer; and a pharmaceutically acceptable carrier.
2. Use of a composition comprising (-) norcisapride or a pharmaceutically acceptable salt thereof, substantially free of its (+) stereoisomer, for the preparation of a medicament for use in the treatment of a disease state such as gastro-esophageal reflux disease and gastrointestinal motility dysfunction.
15
3. A method of treating gastro-esophageal reflux disease in a human while substantially reducing the concomitant liability of adverse effects associated with racemic cisapride, which comprises administering to a human an effective amount of (-) norcisapride, or a pharmaceutically acceptable salt thereof, substantially free of its (+) stereoisomer.
20
4. A method for treating gastro-esophageal reflux disease in a human while achieving a higher bioavailability than is attainable with racemic cisapride, its isomers or racemic norcisapride which comprises administering to a human an effective amount of (-) norcisapride, or a pharmaceutically acceptable salt thereof, substantially free of its stereoisomer.
25
5. A method of eliciting an antiemetic effect in a human while substantially reducing the concomitant liability of adverse effects associated with cisapride, which comprises administering to a human an amount of (-) norcisapride, or a pharmaceutically acceptable salt thereof, substantially free of its (+) stereoisomer.
30
- 35

6. A method of eliciting an antiemetic effect in a human while achieving a higher bioavailability than is attainable with racemic cisapride, its isomers or racemic norcisapride, which comprises administering to a human an 5 amount of (-) norcisapride, or a pharmaceutically acceptable salt thereof, substantially free of its (+) stereoisomer.

7. A method of treating a condition caused by 10 gastrointestinal motility dysfunction in a human, while substantially reducing the concomitant liability of adverse effects associated with cisapride, which comprises administering to a human an amount of (-) norcisapride, or a pharmaceutically acceptable salt thereof, substantially free of its (+) stereoisomer.

15

8. A method of treating a condition caused by 20 gastrointestinal motility dysfunction in a human, while achieving a higher bioavailability than is attainable with racemic cisapride, its isomers or racemic norcisapride, which comprises administering to a human an amount of (-) norcisapride, or a pharmaceutically acceptable salt thereof, substantially free of its (+) stereoisomer.

9. A method of treating a disorder of the central 25 nervous system, selected from the group consisting of cognitive disorders, behavioral disorders, mood disorders, and disorders of control of autonomic function, in a human, which comprises administering to said human an amount of (-) norcisapride or a pharmaceutically acceptable salt thereof, 30 substantially free of its (+) stereoisomer.

10. A method of treating a disease state in a human 35 which comprises administering to a human (a) an effective amount of (-) norcisapride or a pharmaceutically acceptable salt thereof, substantially free of its (+) stereoisomer; and (b) another therapeutic agent.

11. A method of treating a disease state in a human while avoiding adverse drug interactions associated with racemic cisapride which comprises administering to a human
5 (a) an effective amount of (-) norcisapride or a pharmaceutically acceptable salt thereof, substantially free of its (+) stereoisomer; and (b) another therapeutic agent.

12. The method according to claims 7 or 8 wherein said condition caused by gastrointestinal motility dysfunction is
10 selected from the group consisting of dyspepsia, gastroparesis, constipation, post-operative ileus, and intestinal pseudo-obstruction.

13. The method of claims 10 or 11 wherein said disease state is gastro-esophageal reflux, nausea or vomiting, gastrointestinal motility dysfunction or a disorder of the central nervous system.

14. The method of claims 10 or 11 wherein said therapeutic agent is an antifungal, antiviral, antibacterial, antitumor, antihistamine agent or a selective serotonin uptake inhibitor.

15. The method of claims 10 or 11 wherein said therapeutic agent is a drug known to inhibit the cytochrome P450 system.

16. The method of claim 15 wherein said antifungal agent is ketoconazole or itraconazole.

30

17. The method of claims 10 or 11 where (-) norcisapride is administered concurrently or sequentially as said other therapeutic agent.

35 18. The method of claims 3 to 11 wherein (-) norcisapride is administered by transdermal delivery, or orally as a tablet, a capsule or a liquid suspension.

19. The method of claim 18 wherein the amount of (-) norcisapride, or a pharmaceutically acceptable salt thereof, administered is from about 1 mg to about 200 mg per day.

5 20. The method of claim 19 wherein the amount administered is from about 5 mg to about 100 mg per day.

10 21. The method of claim 20 wherein the amount administered is from about 5 mg to about 75 mg per day.

22. The method of claim 18 wherein said amount is administered in divided doses from one to four times per day.

15 23. The method of claims 3 to 11 wherein the amount of (-) norcisapride or a pharmaceutically acceptable salt thereof is greater than approximately 90% by weight of the total weight of norcisapride.

20 24. The method of claims 3 to 11 wherein the amount of (-) norcisapride or a pharmaceutically acceptable salt thereof, substantially free of its stereoisomer is administered together with a pharmaceutically acceptable carrier.

A. CLASSIFICATION OF SUBJECT MATTER
IPC 6 A61K31/445

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)
IPC 6 A61K

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A	JOURNAL OF CHROMATOGRAPHY B, vol. b670, 4 April 1995, QUEENSLAND, AUSTRALIA, pages 139-143, XP000577219 PREECHAGON, B.G. CHARLES ET AL.: "Analysis of cisapride in neonatal plasma using high-performance liquid chromatography with a base-stable column and fluorescence detection" *cf. abstract, introduction* --- -/-	1,2,7,8, 12,13

Further documents are listed in the continuation of box C.

Patent family members are listed in annex.

* Special categories of cited documents :

- *A* document defining the general state of the art which is not considered to be of particular relevance
- *E* earlier document but published on or after the international filing date
- *L* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- *O* document referring to an oral disclosure, use, exhibition or other means
- *P* document published prior to the international filing date but later than the priority date claimed

- *T* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- *X* document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- *Y* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.
- *&* document member of the same patent family

Date of the actual completion of the international search

2 August 1996

Date of mailing of the international search report

13. 08. 96

Name and mailing address of the ISA

European Patent Office, P.B. 5818 Patentlaan 2
